

Scenario B: Short-Job Heavy

Input

Quantum = 2

Process	AT	BT
P1	0	2
P2	1	3
P3	2	1
P4	3	2
P5	4	1

Analysis

- **Which algorithm gave lower average waiting time?**
SJF and SRTF achieved the lowest average waiting time, both outperforming Round Robin.
- **Which algorithm gave lower average response time?**
SJF and SRTF provided lower response times for short processes compared to Round Robin.
- **Did Round Robin appear fairer across all processes?**
Yes. Round Robin distributed CPU time more evenly among all processes.
- **Did SJF complete short jobs more efficiently?**
Yes. Both SJF and SRTF completed short processes immediately after arrival.
- **How did the chosen quantum affect Round Robin behavior?**
The quantum caused processes to wait for repeated turns, increasing waiting and turnaround times.
- **Which algorithm would you recommend for the tested workload, and why?**
SJF or SRTF are recommended because they are highly efficient for workloads dominated by short processes.

Conclusion

- SJF and SRTF performed better than Round Robin in all major metrics.
- Round Robin was more balanced but less efficient.

- SJF and SRTF efficiently handled short processes with minimal waiting time.
- The selected quantum increased waiting time in Round Robin because processes were executed in cycles rather than completed immediately.
